# The Xmas problem

There are three types of Xmas presents Santa Claus can make.

- Santa Claus wants to reduce the overhead by making only two types.
- He needs at least 100 presents.
- He needs at least 5 of either type 1 or type 2.
- He needs at least 10 of the third type.
- Each present of type 1, 2, and 3 need 1, 2, resp. 5 minutes to make.
- Santa Claus is late, and he has only 3 hours left.
- Each present of type 1, 2, and 3 costs 3, 2, resp. 1 EUR.
- He has 300 EUR for presents in total.

$$\begin{aligned} & (p_1 = 0 \vee p_2 = 0 \vee p_3 = 0) \wedge p_1 + p_2 + p_3 \geq 100 \wedge \\ & (p_1 \geq 5 \vee p_2 \geq 5) \wedge p_3 \geq 10 \wedge p_1 + 2p_2 + 5p_3 \leq 180 \wedge \\ & \qquad \qquad \qquad 3p_1 + 2p_2 + p_3 \leq 300 \end{aligned}$$

# Linear arithmetic over the reals

- Goal: decide satisfiability of  
conjunctions of linear constraints over the reals

$$\bigwedge_{1 \leq i \leq m} \sum_{1 \leq j \leq n} a_{ij} x_j \leq b_i$$

- Input in matrix form:  $A\bar{x} \leq \bar{b}$

$$m \text{ constraints} \begin{pmatrix} a_{11} & a_{12} & \cdots & \cdots & a_{1n} \\ a_{21} & a_{22} & \ddots & & \vdots \\ \vdots & & & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & \cdots & a_{mn} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ \vdots \\ x_n \end{pmatrix} \leq \begin{pmatrix} b_1 \\ \vdots \\ \vdots \\ b_m \end{pmatrix}$$

$n$  variables

- Earliest method for solving linear inequalities discovered in 1826 by Fourier, re-discovered by Motzkin in 1936
- Basic idea of variable elimination:
  - Pick a variable and eliminate it, yielding an equisatisfiable formula that does not refer to the eliminated variable any more.
  - Continue until all variables are eliminated.
- Fourier-Motzkin: Put requirements on the **lower an upper bounds** on the variable we want to eliminate.

- For a variable  $x_n$ , we can partition the constraints according to the coefficient  $a_{in}$ :
  - $a_{in} > 0$ : upper bound  $\beta_i$  on  $x_n$
  - $a_{in} < 0$ : lower bound  $\beta_i$  on  $x_n$

$$\sum_{j=1}^n a_{ij} \cdot x_j \leq b_i$$

$$\Rightarrow a_{in} \cdot x_n \leq b_i - \sum_{j=1}^{n-1} a_{ij} \cdot x_j$$

$$(a) \quad a_{in} \begin{matrix} > \\ \Rightarrow \end{matrix} 0 \quad x_n \leq \frac{b_i}{a_{in}} - \sum_{j=1}^{n-1} \frac{a_{ij}}{a_{in}} \cdot x_j \quad =: \beta_l \quad \text{upper bound}$$

$$(b) \quad a_{in} \begin{matrix} < \\ \Rightarrow \end{matrix} 0 \quad x_n \geq \frac{b_i}{a_{in}} - \sum_{j=1}^{n-1} \frac{a_{ij}}{a_{in}} \cdot x_j \quad =: \beta_u \quad \text{lower bound}$$

# Example for upper and lower bounds

	Category for $x_1$ ?
(1) $x_1 - x_2 \leq 0$	Upper bound
(2) $x_1 - x_3 \leq 0$	Upper bound
(3) $-x_1 + x_2 + 2x_3 \leq 0$	Lower bound
(4) $-x_3 \leq -1$	No bound

# Eliminating unbounded variables

- Iteratively remove variables that are not bounded in both ways (and all the constraints that use them).
- The new problem has a solution iff the old problem has one!

$$\begin{array}{l} \cancel{8x} \geq \cancel{7y} \\ \cancel{x} \geq \cancel{3} \\ y \geq z \\ z \geq 10 \\ 20 \geq z \end{array} \quad \longrightarrow \quad \begin{array}{l} \cancel{y} \geq \cancel{z} \\ z \geq 10 \\ 20 \geq z \end{array} \quad \longrightarrow \quad \begin{array}{l} z \geq 10 \\ 20 \geq z \end{array}$$

- For each pair of a lower bound  $\beta_l$  and an upper bound  $\beta_u$ , we have

$$\beta_l \leq x_n \leq \beta_u$$

- For each such pair, add the constraint

$$\beta_l \leq \beta_u$$

<del>(1)</del>	<del><math>x_1 - x_2 \leq 0</math></del>		Category for $x_1$ ?
<del>(2)</del>	<del><math>x_1 - x_3 \leq 0</math></del>		Upper bound
<del>(3)</del>	<del><math>x_1 + x_2 + 2x_3 \leq 0</math></del>		Upper bound
(4)	$-x_3 \leq -1$		Lower bound
<hr/>			Lower bound
(5)	$2x_3 \leq 0$	(from 1,3)	eliminate $x_1$
(6)	$x_2 + x_3 \leq 0$	(from 2,3)	Upper bound
<hr/>			we eliminate $x_3$
(7)	$1 \leq 0$	(from 4,5)	

→ **Contradiction** (the system is UNSAT)

- Worst-case complexity:

$$m \rightarrow m^2 \rightarrow (m^2)^2 \rightarrow \dots \rightarrow m^{2^n}$$

- Heavy!

- The bottleneck: case-splitting
